Prospecting 101

- Exploration

- step-wise sequence to develop ore body valuation.
- Geological reconnaissance, surface geochemical, and geophysical surveys prevail
- exploratory drill holes on select targets

- Feasibility drilling stage.

- close-spaced drilling (“development drilling”)
- outlines deposit geometry in detail.
- extensive testing to precisely determine grade of deposit and the “recovery”
- “reserve drilling” for final assessment
- actual mining or extraction method is proposed,
- considers economic variables (commodity price, milling cost, transportation cost
- mine the deposit from the surface (“open-pit mining”), or to mine the deposit by tunneling (“underground mining”).

- throughout the life of the mine,

- further definition required
- refine the deposit model.

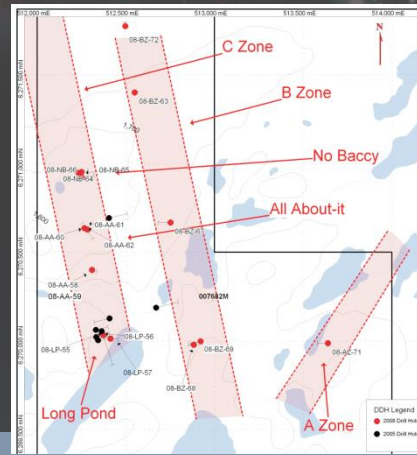

Prospecting 101

- valuation of ore body (“deposit”)
 - “tonnage” (or volume)
 - drill data to delineate subsurface deposit,
 - geometric models to calculate the volume.
 - irregular shaped deposits introduce delineation error
 - “grade” (or concentration)
 - numerous assays to determine average concentration
 - evaluation of “purity” (how is the ore “bound”)
 - can vary considerably within different parts of the same ore body.

Prospecting 101

Prospecting 101

Definition and Assay Methods

- Grade and tonnage evaluations require sample analysis
- Method A: scoop a suite of samples from surface (shallow trenching or “spot” sampling)
 - relies on meteoritic gardening to provide statistically relevant mixing of “ores”
 - Requires a statistically large number of samples
 - Provides weak connection to depth data (no clear definition of stratification, if any)
 - This is required to determine the amount of work required to access the ore (ie overburden, waste removal, trenching methods, etc)
 - Results in 2 D map of “ore body”
- Method B: drill and sample
 - Allows definition of ore in 3rd dimension (depth) (stratification must be maintained during sampling)
 - Requires statistically large number of samples
 - Results in 3D map of ore body
- Sample analysis must be performed (use LIBS, for example)
 - Provides analysis of each sample with indication of grade and vertical position

Mining Design

- Post Assay will yield:
 - Ore body delineation with grade and accessibility (feasibility) definitions
 - Excavation technique required
 - Pilot plant design baseline data (list of “host” contaminants)
 - Do we keep the contaminants and refine those or toss em overboard
 - Refining methodology
 - Power budget
 - Mass budget
 - Time budget (hence ROI)
 - System build up requirements
